## QuickPoll

### Peri-implant Diseases

The incidence of peri-mucositis and peri-implantitis on patients who receive implants is a staggering 20-90% within a period of 5-11 years. There are no definitive interventions associated with successful therapy of peri-implant disease, which is defined as mucosal inflammation surrounding the implant with or without 2 mm or more of bone loss after restoration (implant loading).

Please respond to the [5-question poll](#) regarding treatment modalities and success for peri-implant diseases. We will keep you posted about the results of the quick poll. Your response will help determine whether to consider this for a network study.
